What are Git Aliases?

Git aliases allow you to create **short commands** for frequently used Git operations.

Example:

```
git st  → git status
git co  → git checkout
git cm  → git commit
```

Global Git Aliases

Global aliases work in **all repositories** on your system.

Set a Global Alias

```
git config --global alias.st status
```

Now you can use:

```
git st
```

More Examples

```
git config --global alias.co checkout
git config --global alias.cm commit
git config --global alias.br branch
```

Local Git Aliases

Local aliases work **only inside a specific repository**.

Set a Local Alias

```
git config alias.st status
```

This alias will only work in the current project.

Advanced Alias Example

```
git config --global alias.lg "log --oneline --graph --all"
```

Usage:

```
git lg
```

Shows a clean visual commit history.
